```

Implement and test the decrement operator for tree\_iterator. Determine the appropriate sequence to insert the numbers 1-15 such that the resulting tree is exactly balanced. After using the print\_sideways function to confirm the construction of this tree, test your iterators on the structure. Similarly, create a couple unbalanced trees to demonstrate that both the increment and decrement operators for iterators are debugged. Your decrement operator should correctly decrement the end() iterator. You can use the same "trick" we used in Lab 6 to make this work for ds\_list iterators. Ask a TA if you have any questions.

To complete this checkpoint: Show one of the TAs your iterator decrement code and your tests cases.

## Checkpoint 2

Add a member function called accumulate to the public interface of the ds\_set<T> class, and provide its implementation. The function should take only one argument (of type T) and it should return the results of accumulating all the data values stored in the tree. The argument is the initial value for the accumulation. The function should only use operator+= on type T.

Test your code by showing that this works for both a set of ints, where the accumulate function should sum the values in the set (initial value parameter is 0), and a set of strings, where the accumulate function should concatenate the strings in the set (initial value parameter is ""). Does it matter if the operator+= for type T is *commutative*? How can you control the result of accumulate if it is *not* commutative?

To complete this checkpoint: Show a TA your completed and tested program.
